

SOLANA Terminal — Complete Feature List

Wallet Connection

- Browser wallet support — auto-detects any Wallet Standard extension (Phantom, Solflare, Backpack, Coinbase Wallet, and others), zero configuration
- Private key import — base58, hex, JSON byte array, or comma-separated byte formats
- Seed phrase import — standard BIP39, 12/15/18/21/24 words, selectable derivation path (including custom) with optional 25th-word passphrase
- New wallet generation — create a fresh BIP39 wallet entirely client-side, with a mandatory "I've saved my seed phrase" confirmation before connecting
- Bulk private-key import — paste many private keys at once, each encrypted and saved locally under one shared password

Security & Self-Custody

- 100% client-side signing — private keys and seed phrases never leave the browser; nothing is transmitted to any server
- AES-256-GCM local encryption for saved wallets, keys derived via PBKDF2 (250,000 iterations, SHA-256)
- Multi-wallet vault — store several encrypted wallets on one device, switch between them without disconnecting
- Session auto-lock — automatically disconnects after a period of inactivity (interval set by the site operator)
- Address confirmation step — every connect flow shows the derived address for explicit confirmation, guarding against wrong derivation paths or seed-phrase typos
- Transaction simulation — Send runs a live pre-flight check and shows whether a transaction is expected to succeed *before* you sign it

Portfolio

- Live balance view — SOL and all SPL token holdings (including Token-2022) in one list
- USD valuation — per-asset and total portfolio value
- Automatic token metadata — symbol, name, and logo resolved automatically
- Token watchlist — star frequently used tokens to pin them to the top of every picker
- Dust filter and QR-code receive

Send

- Send SOL or any SPL token, with QR scanning for recipient entry
- "Send Max" with exact-drain calculation — accounts for rent-exemption and live network fees so the wallet lands at precisely zero
- Configurable priority fees (Auto/Slow/Normal/Fast/Custom)
- Pre-signing simulation — catches likely failures before you commit
- Full explorer links on every completed transaction

Bulk Send

- Three amount modes: a specific amount per address, one fixed amount for everyone, or a randomized range per recipient
- Automatic batching for large recipient lists, with per-batch success/failure reporting

Swap

- Token swaps powered by Raydium, with live quotes auto-refreshing every 20 seconds
- Slippage control, percentage-of-balance shortcuts, and a full quote breakdown (rate, minimum received, price impact) before confirming
- Search by name, symbol, or direct mint address — swap any tradeable token, not just the pre-indexed ones

Cross-Chain Bridge

- Bridge Solana assets to other chains via the deBridge protocol, delivered directly to an address you control
- Full fee transparency and live delivery-status tracking, with optional browser notifications on completion

Native SOL Staking

- Stake directly to the platform's recommended validator — no research required
- My Stakes dashboard showing each stake account's live status (Activating / Active / Deactivating / Inactive)
- One-click Unstake and Withdraw, with the network's real minimum-delegation requirement checked and shown upfront

NFTs

- Automatic detection via on-chain Metaplex metadata, gallery view, and direct transfer from the gallery

Transaction History

- Recent activity feed with status, timestamp, and explorer links
- CSV export for accounting and record-keeping

Address Book

- Save frequently used addresses with custom labels for instant reuse across Send and Bridge

Admin Control Panel

A full white-label control layer — every setting below applies instantly, site-wide, with no redeploy.

Branding

- Custom portal name, tagline, and support/contact link — reflected in the header, footer, and browser tab title

Reliability

- Primary + two fallback RPC endpoints with automatic failover and live "Test" buttons — if one provider goes down mid-session, reads transparently switch to the next
- Native staking validator configuration

Access Control

- System-wide kill switch — take the entire platform offline instantly, with a fully custom message
- Scheduled maintenance windows — set an automatic offline period in advance, independent of the manual switch
- Feature toggles — show or hide individual modules (Send, Bulk Send, Swap, Bridge, Staking, NFTs, History, Address Book) per deployment, for a stripped-down white-label build
- Session timeout control — set how long a connected wallet stays active before auto-locking

Content

- Editable security notice shown on the connect screen, with a show/hide toggle
- Promotional banner — custom text and link, shown across the app

Admin Security

- Multiple admin accounts with independent credentials
- Two-factor authentication (TOTP) — compatible with Google Authenticator, Authy, and similar apps
- Session-based login with automatic lockout after repeated failed attempts
- Full activity log — every login, settings change, and account change is recorded with a timestamp

Bullets:

-  **True self-custody** — private keys and seed phrases never leave your browser, never touch our servers
-  **Connect your way** — browser wallet, private key, seed phrase, or generate a brand-new wallet in seconds
-  **Trade, bridge & stake — natively** — swap via Raydium, cross-chain via deBridge, native SOL staking, all in one terminal
-  **Simulated before you sign** — every send is pre-checked against the live network, so you catch a failing transaction before it costs you
-  **Bulk send at scale** — pay out hundreds of wallets in one batch, with per-recipient amounts or randomized ranges
-  **Fully white-labeled** — your branding, your rules: instant kill switch, feature toggles, 2FA-protected admin control, all included
-  **Everything in one dashboard** — balances, NFTs, and transaction history at a glance, with a watchlist to keep your favorite tokens front and center
